Searching for the properly range to fit coincidence histograms

As a first approach, two criteria were considered:

- The χ^2/Ndof
- The error of the peak obtained from the fit; named as ErrIpk, for pulse height histograms and ErrQpk, for charge histograms.

Searching for the properly range to fit coincidence histograms

As a first approach, two criteria were considered:

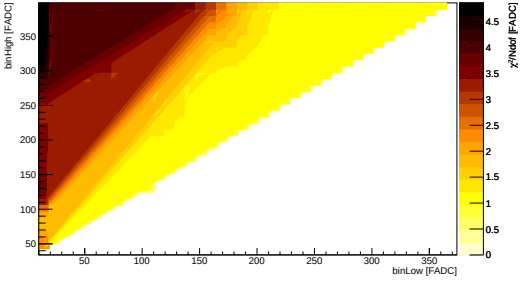
- The χ^2/Ndof
- The error of the peak obtained from the fit; named as ErrIpk, for pulse height histograms and ErrQpk, for charge histograms.

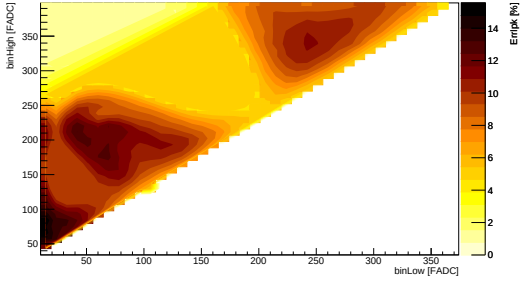
The algorithm was temporally implemented in the SdHistogramFitterKGB.cc module:

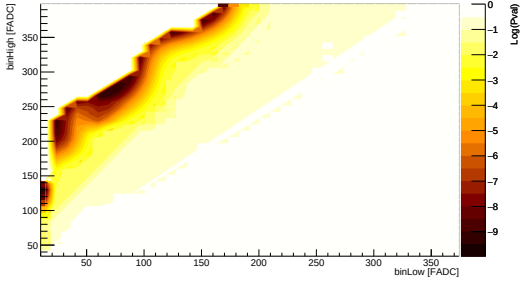
```
for ( int binLow = firstBinLow; binLow < lastBinHigh-5; binLow+=binWidth )
  for ( int binHigh = binLow+(6*binWidth); binHigh < lastBinHigh; binHigh+=binWidth ) {
    [...]
  }
```

Where binWidth takes the value of 4, for height pulse histograms, and 8 for charge histograms. The number 6 corresponds to minimum number of data points, due to we are fitting a second order polynomial.

Results for height pulse histograms







Results for charge histograms
