

Accuracy of Q_{VEM}^{pk} fit for UB and UUB

Mauricio Suárez Durán and Ioana C. Mariş

IIHE-ULB

February 28, 2022

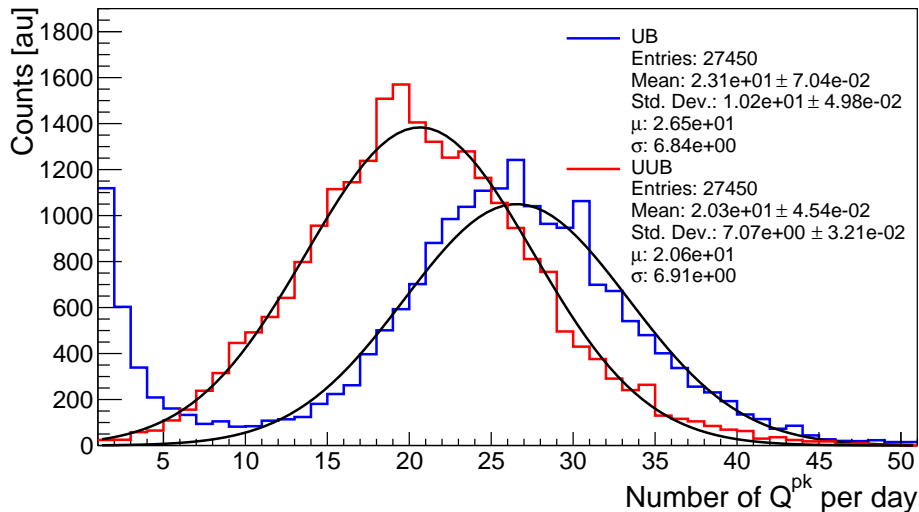

How the moving window works

The goal: To choose the more stable 7-days in a row for fitted Q_{VEM}^{Pk} .

1. An $\langle Q_{\text{VEM}}^{Pk} \rangle$ is calculate per day, then a first 7-day-series of $\langle Q_{\text{VEM}}^{Pk} \rangle$ is built.
2. A linear fit is applied to the 7-day-series, and the respective slope and χ^2 are stored.
3. A new [7-day-series]₁ is built by replacing the seventh day in previous [7-day-series]₀ by next day.
4. A check for continuity is applied, i.e. if 7 days are not consecutive a new series is built, e.g. if series i has a discontinuity in day 3 jumping to day 5, a new 7-day-series is calculated from day 5.

It is possible to see how the average $\langle Q_{\text{VEM}}^{Pk} \rangle_{7\text{days}}$ is moving leftward.

Distribution of Qpk per day

Moving window algorithm results

After a cut for > 10 Qpk per day

Moving window algorithm results

After a cut for $\chi^2 < 10$, Slope $\mu \pm \sigma$, and $\text{Log10(Pval)} > -5.0$

How the accuracy is calculate

1. After the cuts, per station and per PMT, a set of 7-day-series is obtained.
2. If for the same station, a PMT was not chosen, e.g. in UB version, this one is not taken into the account for UUB, and vice versa.
3. With the chosen PMT, a singular normalized distribution is built for UB and UUB version.
4. A Gaussian function is fitted to the normalized distribution and then the accuracy is calculated as: σ/μ , respectively.

How the accuracy is calculate

Accuracy results

For accuracy distribution, only $\sigma/\mu < 5.0 \%$ considered.

Outliers, $\mu/\sigma > 10. \%$

Outliers, $\mu/\sigma > 3.5\%$ and $(\mu/\sigma)_{\text{UB}} - (\mu/\sigma)_{\text{UUB}} < -1. \%$

Outliers, $(\mu/\sigma)_{\text{UB}} - (\mu/\sigma)_{\text{UUB}} < -1. \%$

Outliers, $(\mu/\sigma)_{\text{UB}} - (\mu/\sigma)_{\text{UUB}} < -1. \%$

Outliers, $(\mu/\sigma)_{\text{UB}} - (\mu/\sigma)_{\text{UUB}} > 1. \%$
